(54) Title: METHOD AND DEVICE FOR MODIFYING DATA IN AN ENCODED DATA STREAM

(57) Abstract

A basic transcoder, that decodes an encoded data stream and re-encodes it, may be used for locally modifying data in said stream. Said modification is carried out by defining a predicted data stream on the basis of a given modifying data stream and adding to the decoded stream - between the decoding and re-encoding parts of the transcoder - the difference between the modifying data stream and the predicted one. In an improved implementation, the modifying data stream is preprocessed so that it may be obtained in the decoded data stream a local substitution of said modifying data to the decoded ones.

Method and device for modifying data in an encoded data stream.

FIELD OF THE INVENTION

The present invention relates to a method of modifying data in an encoded data stream corresponding to successive pictures divided into sub-pictures, comprising the steps of:

- decoding said encoded data stream ;
- 5 - re-encoding the decoded data stream.

The invention also relates to a video processing device for carrying out said method. This invention, for instance useful when a broadcaster wants to introduce additional data such as its own logo into a sequence of pictures, finds applications not only in the field of MPEG-2 compression (MPEG-2 will be the common standard for TV broadcasting), but more generally
10. in any digital video data compression system.

BACKGROUND OF THE INVENTION

In such a situation, i.e when additional digital data have to be added before transmission to an existing coded bitstream, the simplest solution is to decode said bitstream
15 before carrying out said addition. The modified bitstream is then re-coded and transmitted. Unfortunately, a full decoding can generally be considered as expensive, as it requires a decoder and an encoder. Moreover, re-encoding with re-estimated modes and vectors may introduce artefacts on the areas left untouched by the logo addition.

20 SUMMARY OF THE INVENTION

It is therefore a first object of the invention to propose a low-cost solution to add data in a previously existing coded bitstream.

To this end, the invention relates to a method such as described in the opening paragraph of the description and which is moreover characterized in that it also comprises the
25 steps of :

- defining a predicted data stream on the basis of an input modifying data stream ;
- adding to the decoded data stream, before re-encoding it, the difference between the modifying data stream and the predicted one.

This method has for effect to convert the additional data, thanks to the mixing step, into a specific correcting signal that can then be added to the residue signal of the transcoder.

Another object of the invention is to propose an improved method for carrying
5 out an insertion of data with an improved quality with respect to said addition of data.

To this end the invention relates to a method characterized in that it also comprises the step of preprocessing the modifying data stream in order to obtain in the decoded bitstream a substitution of said modifying data to the decoded ones.

Another object of the invention is also to propose devices for implementing the
10 above-mentioned methods.

To this end the invention relates, in a first implementation, to a device for adding data to a video coded data stream, characterized in that it comprises :

- (1) a transcoder, for decoding said data stream and re-encoding it ;
- (2) an addition branch, for defining :

15 (i) on the basis for these additional data and motion vectors defined in the transcoder, a predicted signal ;
(ii) the difference between said additional data and said predicted signal, in view of an addition of said difference into said data stream between decoding and re-encoding parts of said transcoder.

20 The invention also relates, in a second implementation, to a device for inserting data into a video coded data stream, characterized in that it comprises :

- (1) a transcoder, for decoding said bitstream and re-encoding it ;
- (2) an insertion branch, for defining :

(i) on the basis of these additional data a preprocessed signal ;
25 (ii) on the basis of said preprocessed signal and motion vectors defined in the transcoder, a predicted signal ;

(iii) the difference between said preprocessed additional data and said predicted signal, in view of an insertion of said difference into said bitstream between decoding and re-encoding parts of said transcoder.

30 In the US patent N° 5691986, a method and apparatus for inserting data into an encoded data stream are described. However, in the situation as described, said stream is in fact a multiplex of elementary data streams that have to be demultiplexed in order to extract one of these elementary streams, to perform a data reduction operation on this extracted stream, and to insert said data into the reduced data stream. The present invention has a

distinct object, which is either the addition of data in a picture or, in an improved embodiment, the local replacement of a part of a picture by other picture data.

BRIEF DESCRIPTION OF THE DRAWINGS

5 These and other aspects of the invention will be apparent from and elucidated with reference to the embodiment described hereinafter.

In the drawings :

- Figs.1 and 2 show conventional video decoder and encoder ;
- Fig.3 shows a possible scheme of a transmission chain for adding a log to an
10 incoming bitstream ;
- Fig.4 illustrates the outline of a known transcoder, without logo adder ;
- Fig.5 illustrates such a transcoder when it is, according to the invention,
provided with a logo adder ;
- Fig.6 also illustrates such a transcoder, but when it is, according to the
15 invention, provided with a logo insertion device ;
- Fig.7 illustrates a computation made in said logo insertion device ;
- Figs.8 to 10 illustrate the processing carried out on the luminance and
chrominance components, and Figs. 11 and 12 a logo clipping carried out after said
processings.

20

DESCRIPTION OF THE INVENTION

A conventional video decoder such as shown in Fig.1 includes a decoding channel 12, which comprises in cascade a variable length decoding circuit 1, an inverse quantizing circuit 2 and an inverse frequency transform circuit 3 (respectively : VLD, IQ,
25 IDCT), and a motion compensation channel 14, which comprises a picture memory 4 receiving the output signals of the decoder, a motion compensation circuit 5 (said compensation taking into account the output signals of this memory 4 and motion vectors $V(n)$ received by the decoder) and an adder 6 of the output signals of circuits 3 and 5 (respectively : MEM, COMP, A). The output picture of the decoder (also sent to the picture memory 4) is
30 reconstructed by adding the prediction (output of circuit 5) to the decoded residual signal available at the output of the circuit 3 of the decoding channel 12.

A conventional video encoder such as shown in Fig.2 includes an encoding and decoding channel 13, which comprises a discrete cosine transform circuit 25, a quantizing circuit 26, a variable length coding circuit 27 (respectively : DCT, Q, VLC) and, at the output

of the circuit 26, in cascade, an inverse quantizing circuit 28 and an inverse discrete cosine transform circuit 29 (respectively : IQ and IDCT), and a prediction channel 11, allowing to subtract a motion compensated prediction from the input signal and which comprises an adder 21, for the reconstruction of the pictures before prediction, a picture memory 22, a motion
 5 compensation circuit 23 and a subtracter 24 (respectively : A, MEM, COMP, S). Said compensation takes into account previously estimated motion vectors $V(n)$.

A possible method and a device allowing to add data such as a logo to an incoming bitstream in a transmission chain are illustrated in Fig.3. Said chain comprises a first encoder 31 (called "encoder 1"), a sub-system 305 for the addition of the logo to the coded
 10 bitstream available at the output of the encoder 31, and, after transmission, a decoder 35 ("decoder 2"). The sub-system provided between said encoder and decoder itself comprises, as illustrated, a decoder 32 ("decoder 1"), a logo adder 33 and an encoder 34 ("encoder 2"). Then, starting from said decoder 32 and said encoder 34 and taking advantage of their complementarity, some simplifications will be made, in order to finally reach the outline of the
 15 transcoder according to the invention.

According to Fig.2, one has indeed, for the first encoder 31 :

$$R(n,1) = I(n) - P(I'(n-1), 1 ; V(n)) \quad (1)$$

where the index (,1) in $R(.)$ and $P(.)$ designates the "first" encoder 31 (= encoder 1), $I(n)$ is the original video input of the encoder, $P(I'(n-1), 1 ; V(n))$ is the prediction signal computed by
 20 applying motion vector $V(n)$ to the previously "decoded" picture $I'(n-1)$ and which has to be subtracted from the original input bitstream $I(n)$ in order to obtain the residual signal $R(n)$ to be coded, and $R(n)$ designates this residual signal. It must be noted that the signal $R'(n)$ available at the input of the prediction channel of the encoder differs from $R(n)$ by a value $e(n)$ called the coding error ; $R'(n)$ being equal to $R(n) + e(n)$, the signal at the output of the adder
 25 of this prediction channel is therefore $I'(n) = I(n) + e(n)$.

For the first decoder 32 that follows the encoder 31, one has similarly, according to Fig.1 :

$$I'(n,1) = R'(n,1) + P(I'(n-1), 1 ; V(n)) \quad (2)$$

where the index (,1) in $I'(.)$, $R'(.)$ and $P(.)$ designates the "first" decoder 32, $R'(n)$ is the decoded residual signal, $P(I'(n-1), 1 ; V(n))$ is the prediction to be added to $R'(n)$, and $I'(n)$
 30 designates the output of the decoder. As seen above, $I'(n,1)$ may also be written in the form :

$$I'(n,1) = I(n) + e(n,1)$$

that is to say, the output of the decoder is the sum of the original input signal $I(n)$ and of the coding error $e(n)$ during the coding operation of $I(n)$. At the output of the logo adder 33, one has consequently :

$$J'(n,1) = I'(n,1) + \text{Logo}(n) \quad (3)$$

5 where $I'(n)$ is the output of the decoder 32 and $\text{Logo}(n)$ the data (for instance, a logo) to be added to the main bitstream. The resulting output $J'(n)$ is sent towards the encoder 34.

For this second encoder 34, one has (similarly to the previous case of the first encoder 31) :

$$R(n,2) = J'(n,1) - P(J'(n-1), 2 ; V(n)) \quad (4)$$

10 where the index $(,2)$ in $R(.)$ and $P(.)$ now designates this "second" encoder 34, $P(J'(n-1), 2 ; V(n))$ is the prediction which has to be subtracted from the output $J'(n-1)$ of the logo adder 33 in order to obtain the residual signal that has to be coded, and $R(n)$ designates said residual signal.

Finally, for the second decoder 35, one has (similarly to the previous case of the first decoder 32) :

$$J'(n,2) = R'(n,2) + P(J'(n-1), 2 ; V(n)) \quad (5)$$

where the index $(,2)$ in $J'(.), R'(.)$ and $P(.)$ now designates this "second" decoder 35, $R'(n)$ is the decoded residual signal, $P(J'(n-1), 2 ; V(n))$ is the prediction to be added to $R'(n)$, and $J'(n)$ designates the output of the decoder. As for the decoder 32, $J'(n,2)$ may be also be

20 written in the form :

$$J'(n,2) = J'(n,1) + e(n,2)$$

$$J'(n,2) = I'(n,1) + \text{Logo}(n) + e(n,2)$$

$$J'(n,2) = I(n) + e(n,1) + \text{Logo}(n) + e(n,2) \quad (6)$$

which means that the output signal $J'(n,2)$ of the transmission chain is indeed equal to the sum of the original input signal $I(n)$, of the first coding error (coding/decoding in the first encoder and decoder), of the second coding error (coding/decoding in the second encoder and decoder), and of the additional data.

Then, using the linearity of the motion compensation operator, it may be written:

$$30 \quad P(J'(n-1), 2 ; V(n)) = P[(J'(n-1), 1) + (e(n-1), 2) ; V(n)] \quad (7)$$

which allows to write the relation (4) in the form :

$$R(n,2) = J'(n,1) - P[(J'(n-1), 1) + (e(n-1), 2) ; V(n)] \quad (8)$$

Using again the linearity of the compensation operator, one has :

$$P(J'(n-1), 1 ; V(n)) = P[(I'(n-1) + \text{Logo}(n-1)), 1 ; V(n)]$$

or :

$$P(J'(n-1), 1 ; V(n)) = P(I'(n-1), 1 ; V(n)) + P(\text{Logo}(n-1), 1 ; V(n)) \quad (9)$$

Therefore the relation (8) becomes :

$$\begin{aligned} R(n,2) &= I'(n,1) + \text{Logo}(n) - P(e(n-1),2 ; V(n)) \\ &- P(I'(n-1), 1 ; V(n)) - P(\text{Logo}(n-1), 1 ; V(n)) \end{aligned} \quad (10)$$

or, from the relation (2) :

$$\begin{aligned} R(n,2) &= R'(n-1) - P(e(n-1), 2 ; V(n)) \\ &+ \text{Logo}(n) - P(e(n-1),2 ; V(n)) \\ &- P(I'(n-1), 1 ; V(n)) - P(\text{Logo}(n-1), 1 ; V(n)) \end{aligned} \quad (11)$$

10 which finally leads to the following relation (12) :

$$\begin{aligned} R(n,2) &= R'(n-1) - P(e(n-1), 2 ; V(n)) \\ &+ \text{Logo}(n) - P(\text{Logo}(n-1) ; V(n)) \end{aligned} \quad (12)$$

which is the final system equation of the transcoder with logo adder as proposed according to the invention.

15 The general outline of the transcoder without logo adder is first recalled in Fig.4 (for comparison with Fig.5). It comprises a residue decoding branch 41 (variable length decoding VLD + inverse quantization IQ + inverse discrete cosine transform IDCT), an encoding and decoding branch 42 (discrete cosine transform DCT + quantization Q + variable length coding VLC ; inverse quantization IQ + inverse discrete cosine transform IDCT), and
20 an intermediary branch called a pseudo-prediction branch 43 (first subtracter S + memory MEM + motion compensation COMP on the basis of motion vectors V(n) + second subtracter S). This branch 43 is so called because it is not exactly a classical prediction as in a basic encoder, the first adder being here replaced by a subtracter. The signals R'(n,1), R(n,2), R'(n,2), e(n,2), V(n), P(e(n-1), 2 ; V(n)) previously cited are shown in Fig.4.

25 The corresponding scheme of the transcoder according to the invention -i.e. with a logo adder- is then illustrated in Fig.5 where, in comparison with Fig.4, the identical parts are designated in the same manner. The additional part is a logo addition branch 50 that includes a memory MEM 51, receiving the logo to be added (signal Logo(n)), a motion compensation circuit COMP 52, receiving the output of the memory 51 and the vectors V(n)
30 and delivering a predicted data stream, a subtracter S 53, for delivering the difference between the original signal Logo(n) and the motion compensated one P(Logo(n-1) ; V(n)) available at the output of the circuit 52 (predicted data stream), and an adder 54, for introducing the output signal of said subtracter 53 into the main bitstream (corresponding to the complete sequence of successive pictures). The logo addition is therefore implemented by means of a residue

addition to the incoming bitstream, and this residue is formed by subtracting logo with a motion compensated logo prediction that is based on reference pictures containing logo previously stored and that uses the same modes and vectors as the main incoming bitstream.

The method and device hereabove described may be further improved. It is indeed contemplated no longer to add, but to insert additional data (such as a logo) into the main video bitstream, without modifying the other parts of the picture.

Such an insertion of data, i.e. the replacement of an area of a picture (or sequence of pictures) by said data- is a non-linear processing that requires a full access to the original pixels (= picture elements). For a high quality logo insertion, a full decoding of the incoming bitstream should therefore be performed. According to the invention, such a full decoding is replaced by a low-cost rough decoding (here described in the case of the MPEG-2 standard).

The corresponding scheme of the transcoder according to the invention -i.e. with a logo inserter - is illustrated in Fig.6 where, in comparison with Fig.4, the identical parts are designated in the same manner. The additional part (with respect to Fig.4) is a logo insertion device 400 that will be now described in a detailed manner.

In this logo insertion device, four steps are implemented. The first one is a so-called DC estimation step, carried out in an estimation stage 410. Each picture of an MPEG sequence is subdivided into motion compensation units called macroblocks. Moreover, in MPEG standard, three types of pictures are considered : I (or intra) pictures, coded without any reference to other pictures, P (or predicted) pictures, coded with reference to a past picture (I or P), and B (or bidirectionally predicted) pictures, coded with reference to a past and a future picture (I or P). These I and P pictures will be called reference frames. In the stage 410, the average value of each macroblock is estimated according to the average values of the reference frames (previously stored in associated buffer memories 401 and 402) and to the current average value of the incoming residue (the signal referenced $R'(n,1)$ in Fig.4). If $DCP(b,Y)$ designates the average value of the prediction $PR(b,Y)$ for the macroblock b in the component Y (an illustration of such a computation is given in Fig.7 in the case of an interpolated macroblock : the macroblock in each of the two reference pictures and the prediction $PR(b,y)$ and its average value $DCP(b,Y)$ are shown), if $ACR(b,Y)$ designates the average value of the residue (i.e. of the signal called $R'(n,1)$ at the output of the residue decoding branch 41 of the transcoder) for the same macroblock in the same component Y , and if $MDC(b,Y)$ designates the estimated average value of the same macroblock b in the same component Y , then one has :

$$\text{MDC}(b,Y) = \text{DCP}(b,Y) + \text{ACR}(b,Y) \quad (13)$$

The description is given in the case of the component Y, but it would be the same with anyone of the chrominance components U,V in place of the luminance Y.

It may be observed that no noticeable drift may occur on such estimations if it is assumed that the incoming bitstream, at the input of the transcoder, presents a standard broadcasting GOP duration (e.g. $N = 12$) allowing prediction pictures to be refreshed often enough on intra pictures (a GOP, or Group Of Pictures, consists of an I picture and all succeeding pictures until the next I picture, itself not included, and N is therefore defined as the size of the GOP, the most common one in MPEG standard being $N = 12$).

The second step is a logo processing one, carried out in a processing stage 420. A processing of the logo pixel values is indeed performed in order to keep visibility and conformance of the logo whatever the picture content. It is in fact wanted to have :

$$\text{MV}(\text{CP}) + \text{MV}(\text{Logo}(\text{CP})) = \text{RQM}(\text{CP}) \quad (14)$$

where CP designates the luminance component Y or anyone of the chrominance components (U,V), $\text{MV}(\text{CP})$ is the average value of the original area where the logo has to be inserted in the component CP (these values are estimated according to the relation (13) indicated above), $\text{MV}(\text{Logo}(\text{CP}))$ is the average value of the processed logo, and $\text{RQM}(\text{CP})$ corresponds to the required average value of the picture after logo insertion, in the logo area. The pixel values $\text{Logo}(b, \text{CP})$ of the logo to be inserted at the macroblock b are therefore defined, after logo processing, by the relation (15) :

$$\begin{aligned} \text{Logo}(b, \text{CP}) &= \text{Logo_ori}(b, \text{CP}) + \text{RQM}(\text{CP}) \\ &\quad - \text{MV}(\text{CP}) - \text{MV_Logo_ori}(\text{CP}) \end{aligned} \quad (15)$$

where $\text{Logo_ori}(b, \text{CP})$ designate the original pixel values of the logo to be inserted at the macroblock b, and $\text{MV_Logo_ori}(\text{CP})$ designates the average value of the original logo in the component CP.

This logo processing is illustrated in Figs.8 to 10 : Fig.8 shows the original logo signal $\text{Logo_ori}(b, \text{CP})$ before insertion, its average value $\text{MV_Logo_ori}(\text{CP})$, $\text{RQM}(\text{CP})$, and $\text{MV}(\text{CP})$, while Fig.9 shows what is required ($\text{MV}(\text{CP}) + \text{Logo}(b, \text{CP}) = \text{RQM}(\text{CP})$) and Fig.10 illustrates the principe of the adaptation carried out to obtain the required result (as indicated, a shift of the logo signal of a value equal to $(\text{MV}(\text{CP}) - \text{RQM}(\text{CP})) + \text{MV_Logo_ori}(\text{CP})$).

For chrominance components, logo conformance to the original logo is required, i.e. the insertion of the processed logo into the picture must lead to the colors of the original logo. For the chrominance components U and V, $\text{RQM}(\text{CP})$ is therefore $\text{MV_Logo_ori}(\text{CP})$. For luminance, a choice can be made between either preferring

conformance to the original (i.e. $RQM(Y) = MV_Logo_ori(Y)$) or visibility (so that the logo appears dark in bright areas and vice-versa). In this last case, $RQM(Y) = 128$.

The third step is a logo clipping one, carried out in a clipping stage 430.

According to the MPEG-2 standard, at the decoder side the reconstructed pictures stored in memories are clipped between 0 and 255. To do the same at the encoder side cannot be achieved since a complete decoding of the incoming bitstream is not performed. The clipping step is then performed on a macroblock basis. The right pixel values are not known, but this situation is compensated by taking a margin MG on the clipping. Then, for each component Y, U or V (always called CP), $Logo(b, CP)$ is clipped so that :

$$O + MG < MV(b, CP) + Logo(b, CP) < 255 - MG \quad (16)$$

which gives :

$$MG - MV(b, CP) < Logo(b, CP) \quad (17)$$

$$Logo(b, CP) < 255 - MG - MV(b, CP) \quad (18)$$

This logo clipping is illustrated in Figs. 11 and 12, where Fig.11 allows to represent $MV(b, CP)$, $MV(b, CP) + Logo(b, CP)$, and the clipping limits MG and $255 - MG$, and therefore illustrates the relation (16), while Fig.12 illustrates similarly the relations (17) and (18).

The fourth step is a logo addition one, carried out in a logo addition stage 440 that is identical to the logo addition branch 50 shown in Fig.5. Said stage 440 comprises a memory receiving the clipped logo available at the output of the clipping stage 430, a motion compensation circuit receiving the output of said memory and the vectors $V(n)$ defined in the transcoder, a subtracter (for delivering the difference between the clipped logo, available at the output of the preprocessing part of the logo insertion device 400, and the motion compensated one available at the output of said motion compensation circuit) and an adder (for inserting the output signal of said subtracter into the main bitstream). These four elements (memory, motion compensation circuit, subtracter, adder) are similar to the four elements 51 to 54 of Fig.5. The logo insertion is therefore implemented by means of a residue addition to the incoming bitstream, and this residue is formed by defining the difference between the logo (preprocessed as described) and a motion compensated prediction derived from said preprocessed logo and that uses the same motion vectors as the main incoming bitstream.

CLAIMS:

1. A method of modifying data in an encoded data stream corresponding to successive pictures divided into sub-pictures, comprising the steps of :
- decoding said encoded data stream ;
 - re-encoding the decoded data stream ;
- 5 characterized in that it also comprises the steps of :
- defining a predicted data stream on the basis of an input modifying data stream ;
 - adding to the decoded data stream, before re-encoding it, the difference between the modifying data stream and the predicted one.
- 10
2. A method according to claim 1, in which a pseudo-prediction sub-step is provided between said decoding and re-encoding steps, said sub-step comprising in series the following operations :
- a definition operation of a coding error appeared during the re-encoding step ;
- 15
- a motion compensation operation on the basis of motion vectors previously determined for each respective sub-picture and applied to said coding error ;
 - a subtracting operation defining a residual signal by difference between the decoded data stream and the output stream of the motion compensation operation ;
- said method being characterized in that said definition step comprises the operations of :
- 20
- storing the modifying data stream ;
 - compensating motion on the basis of said motion vectors applied to said stored data stream ;
 - subtracting from the modifying data stream the predicted data stream available after said motion compensation operation.
- 25
3. A video processing device for adding data to a video coded data stream, characterized in that it comprises :
- (1) a transcoder, for decoding said data stream and re-encoding it ;
 - (2) an addition branch, for defining :

(i) on the basis for these additional data and motion vectors defined in the transcoder, a predicted signal ;

(ii) the difference between said additional data and said predicted signal, in view of an addition of said difference into said data stream between decoding and re-
5 encoding parts of said transcoder.

4. A method according to anyone of claims 1 and 2, characterized in that it also comprises the step of :

- preprocessing the modifying data stream in order to obtain in the decoded data
10 stream a substitution of said modifying data to the decoded ones.

5. A method according to claim 4, in which a pseudo-prediction sub-step is provided between said decoding and re-encoding steps, said sub-step comprising in series the following operations :

15 - a definition operation of a coding error appeared during the re-encoding step ;
- a motion compensation operation on the basis of motion vectors previously determined and applied to said coding error ;

- a subtracting operation defining a residual signal by difference between the decoded data stream and the output stream of the motion compensation operation ;

20 said method being characterized in that said preprocessing step includes the operations of :
- estimating the average values of all the sub-pictures of the current picture corresponding to said data stream ;

- preprocessing the additional data in order to keep visibility and conformance of the additional data whatever the picture content is ;

25 - clipping said preprocessed additional data on a macroblock basis.

6. A video processing device for inserting data into a video coded data stream, characterized in that it comprises :

(1) a transcoder for decoding said data stream and re-encoding it ;

30 (2) an insertion branch, for defining :

(i) on the basis of these additional data a preprocessed signal ;

(ii) on the basis of said preprocessed signal and motion vectors defined in the transcoder, a predicted signal ;

(iii) the difference between said preprocessed additional data and predicted signal, in view of an insertion of said difference into said data stream between decoding and re-encoding parts of said transcoder.

INTERNATIONAL APPLICATION PUBLISHED UNDER THE PATENT COOPERATION TREATY (PCT)

(51) International Patent Classification ⁶ : H04N 7/26, 7/50, 7/08, 5/272		A3	(11) International Publication Number: WO 99/51033
			(43) International Publication Date: 7 October 1999 (07.10.99)
(21) International Application Number: PCT/IB99/00235		(81) Designated States: BR, CN, JP, KR, European patent (AT, BE, CH, CY, DE, DK, ES, FI, FR, GB, GR, IE, IT, LU, MC, NL, PT, SE).	
(22) International Filing Date: 11 February 1999 (11.02.99)		Published With international search report. Before the expiration of the time limit for amending the claims and to be republished in the event of the receipt of amendments.	
(30) Priority Data: 98400759.1 31 March 1998 (31.03.98) EP 98400802.9 3 April 1998 (03.04.98) EP		(88) Date of publication of the international search report: 18 November 1999 (18.11.99)	
(71) Applicant: KONINKLIJKE PHILIPS ELECTRONICS N.V. [NL/NL]; Groenewoudseweg 1, NL-5621 BA Eindhoven (NL).			
(71) Applicant (for SE only): PHILIPS AB [SE/SE]; Kottbygatan 7, Kista, S-164 85 Stockholm (SE).			
(72) Inventor: BAILLEUL, Nicolas; Prof. Holstlaan 6, NL-5656 AA Eindhoven (NL).			
(74) Agent: LANDOUSY, Christian; Prof. Holstlaan 6, NL-5656 AA Eindhoven (NL).			

(54) Title: METHOD AND DEVICE FOR MODIFYING DATA IN AN ENCODED DATA STREAM

(57) Abstract

A basic transcoder, that decodes an encoded data stream and re-encodes it, may be used for locally modifying data in said stream. Said modification is carried out by defining a predicted data stream on the basis of a given modifying data stream and adding to the decoded stream - between the decoding and re-encoding parts of the transcoder - the difference between the modifying data stream and the predicted one. In an improved implementation, the modifying data stream is preprocessed so that it may be obtained in the decoded data stream a local substitution of said modifying data to the decoded ones.

FOR THE PURPOSES OF INFORMATION ONLY

Codes used to identify States party to the PCT on the front pages of pamphlets publishing international applications under the PCT.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/IB 99/00235

A. CLASSIFICATION OF SUBJECT MATTER

IPC6: H04N 7/26, H04N 7/50, H04N 7/08, H04N 5/272
According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC6: H04N

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

SE,DK,FI,NO classes as above

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

WPI

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	WO 9619077 A1 (PHILIPS ELECTRONICS N.V.), 20 June 1996 (20.06.96), see whole document --	1-6
A	EP 0690392 A1 (PHILIPS ELECTRONICS N.V.), 3 January 1996 (03.01.96), see whole document --	1-6
P,A	DE 19717453 A1 (ROHDE & SCHWARZ GMBH & CO), 5 November 1998 (05.11.98), column 3, line 16 - line 23 --	1-6
E	EP 0936814 A1 (CANAL+SOCIETE ANONYME), 18 August 1999 (18.08.99), see whole document -- -----	1-6

☐ Further documents are listed in the continuation of Box C.☒ See patent family annex.

* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"I" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"I" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance: the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance: the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

Date of the actual completion of the international search

21 Sept 1999

Date of mailing of the international search report

24 -09- 1999

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☐ **BLACK BORDERS**
- ☐ **IMAGE CUT OFF AT TOP, BOTTOM OR SIDES**
- ☐ **FADED TEXT OR DRAWING**
- ☐ **BLURRED OR ILLEGIBLE TEXT OR DRAWING**
- ☐ **SKEWED/SLANTED IMAGES**
- ☐ **COLOR OR BLACK AND WHITE PHOTOGRAPHS**
- ☐ **GRAY SCALE DOCUMENTS**
- ☐ **LINES OR MARKS ON ORIGINAL DOCUMENT**
- ☒ **REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY**
- ☐ **OTHER:** _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
